DESCRIPTIVE SET THEORETICAL COMPLEXITY OF RANDOMNESS NOTIONS

LIANG YU

ABSTRACT. We study the descriptive set theoretical complexity of various randomness notions.

1. Introduction

The original motivation of this paper is to characterize weakly-2-random reals by the prefix-free Kolmogorov complexity. Since Schnorr characterized Martin-Löf randomness by the prefix-free Kolmogorov complexity, many people thought that every randomness notion should have a characterization by the initial segment complexity. For example, Miller and others obtained a very successful characterization of 2-randomness.

Theorem 1.1 (Miller [8] and [9]; Nies, Stephen and Terwijn [12]). A real $x$ is 2-random if and only if

$$\exists c \forall n \exists m (C(x \upharpoonright m) \geq m - c)$$

if and only if

$$\exists c \forall n \exists m > n (K(x \upharpoonright m) \geq m + K(m) - c).$$

Recently, Miller and Yu [10] obtained the following result.

Theorem 1.2 (Miller and Yu [10]). $x \oplus y$ is random if and only if

$$\exists c \forall n (K(x \upharpoonright n) + C(y \upharpoonright n) \geq 2n - c).$$

The theorem gives almost all the “relativizable” randomness notions stronger than Martin-Löf randomness unrelativized Kolmogorov complexity characterizations. An important question remaining open is whether there is a Kolmogorov complexity characterization for weak-2-randomness. This question has been tried by many ways. For example, one way is to ask whether there is a sequence of functions $\{f_n\}_{n \in \omega}$ so that for every real $x$, $x$ is weakly-2-random if and only if $\exists n \forall m \exists k \geq m (K(x \upharpoonright k) \geq k + f_n(k))$? Most of these attempts turned to be some kind of $\Sigma^0_3$-characterizations for weak-2-randomness. But all of the ways (of course) failed. So people suspected that the collection of weakly-2-random reals is not $\Sigma^0_3$. We confirm the doubt.

Then we also study the descriptive set theoretical complexity of some other classical randomness notions. Many results have been obtained in [5] by using Wade reductions. Given two sets of reals $A$ and $B$, $A$ is Wade reducible to $B$, writing to $A \leq_W B$, if there is a continuous functions $f : 2^\omega \to 2^\omega$ so that for every $x$, $x \in A$ if and only if $f(x) \in B$. They prove, for example, that the collection of Schnorr random reals is $\Pi^0_3$-complete (and so non-$\Sigma^0_3$). Here we give another more direct way, by using forcing argument, to prove our results. One may think that the results in [5] are stronger since what they prove is that the collection of Schnorr random reals is $\Pi^0_3$-complete. Actually it is not by the following well known descriptive set theory result.

The author is partially supported by NSF of China No. 10701041, Research Fund for the Doctoral Program of Higher Education, No. 20070284043 and China-US (NSFC-NSF) collaboration grants. We thank Lempp, Miller and Ng for their helpful discussions and the University of Wisconsin-Madison for its hospitality.
Theorem 1.3 (Folklore). For any $\xi < \omega_1$ and $\Sigma^0_\xi$ (or $\Pi^0_\xi$) set $A$, if $A$ is not $\Pi^0_\xi$ (or $\Sigma^0_\xi$), then every $\Sigma^0_\xi$ set is Wade reducible to $A$.

Theorem 1.3 is an immediate conclusion of Borel determinacy. Moreover, our technique results are interesting independently. For example, we prove that the forcing notion of $\Pi^0_3$-classes with computable positive measures does not produce a Martin-Löf random real.

We also study the complexity of the collection of $\Delta^1_3$-random reals. Sacks essentially proves that the collection of $\Delta^1_3$-random reals is $\Pi^0_3$. Hjorth and Nies introduced $\Pi^0_1$-Martin-Löf randomness in [6], which is an analog to the classical Martin-Löf randomness in higher recursion theory. But it was a very difficult question whether $\Pi^0_1$-Martin-Löf randomness is different with $\Delta^1_3$-randomness.

The separation of $\Pi^0_1$-Martin-Löf randomness from $\Delta^1_3$-randomness was given in [2]. The proof in the paper is fairly involved. Only a sketch was presented there. Now we can give a full proof by a simpler argument. Further more, we have a total characterization where $\Delta^1_3$-randomness is different with $\Pi^0_1$-Martin-Löf randomness.

We organize the paper as follows: In section 2, we give some basic definitions. In section 3, we present some easy facts about the descriptive set theoretical complexity of various randomness notions. Most of them are probably known; In section 4, we prove that the collection of weakly-2-random reals is not $\Sigma^0_3$; In section 5, we prove that the collection of Schnorr random reals is not $\Sigma^0_3$; In section 6, we prove that the collection of $\Delta^1_3$-random reals is not $\Sigma^0_3$.

2. Preliminary

A real is Kurtz random if it does not belong to any $\Pi^0_1$-null set. Since co-null open $\Sigma^0_3$ set is dense, every weakly 1-generic real is Kurtz random.

A Schnorr test is an uniformly c.e. sequence of open sets $\{U_n\}_{n \in \omega}$ so that $\mu(U_n) = 2^{-n}$ for every $n$. A real $x$ is Schnorr random if for every Schnorr test $\{U_n\}_{n \in \omega}$, $x \notin \bigcap_{n \in \omega} U_n$. This is equivalent to that $x \notin \bigcap_{n \in \omega} U_n$ for any c.e. sequence of open sets $\{U_n\}_{n \in \omega}$ so that $\mu(U_n) = 2^{-f(n)}$ for every $n$ where $f$ is a computable function from $\omega$ to $[0,1]$ such that $\lim_{n \to \infty} f(n) = 0$.

A Martin-Löf test is an uniformly c.e. sequence of open sets $\{U_n\}_{n \in \omega}$ so that $\mu(U_n) < 2^{-n}$ for every $n$. A real $x$ is Martin-Löf random (or 1-random) if for every Martin-Löf test $\{U_n\}_{n \in \omega}$, $x \notin \bigcap_{n \in \omega} U_n$. There exists a universal Martin-Löf test.

A generalized Martin-Löf test is an uniformly c.e. sequence of open sets $\{U_n\}_{n \in \omega}$ so that $\lim_{n \to \infty} \mu(U_n) = 0$ for every $n$. A real $x$ is weakly-2-random if for every generalized Martin-Löf test $\{U_n\}_{n \in \omega}$, $x \notin \bigcap_{n \in \omega} U_n$. There exists a universal Martin-Löf test. Hirschfeldt and Miller proved the following nice result.

Theorem 2.1 (Hirschfeld and Miller [4]). A real $x$ is weakly-2-random if and only if $x$ is 1-random and does not Turing-compute any non-computable $\Delta^0_2$-real.

For some information about higher randomness, please see [13], [6] and [2]. A real is $\Delta^1_3$-random if and only if it does not belong to any $\Delta^1_3$-null set. It is essentially due to Sacks [13] that a real $x$ is $\Delta^1_3$-random if and only if for any $\Delta^1_3$-sequence of $\Delta^1_3$ open sets $\{U_n\}_{n \in \omega}$ for which $\lim_{n \to \infty} \mu(U_n) = 0$, $x \notin \bigcap_{n \in \omega} U_n$. So the collection of $\Delta^1_3$-random reals is $\Pi^0_3$.

A $\Pi^0_1$-Martin-Löf test is a $\Pi^0_1$-sequence of $\Pi^0_1$-coded open sets $\{U_n\}_{n \in \omega}$ (i.e. the set $\{(n,\sigma) \mid \sigma \in U_n\}$ is $\Pi^0_1$) so that $\mu(U_n) < 2^{-n}$ for every $n$. Hjorth and Nies proved that there is a universal $\Pi^0_1$-Martin-Löf test. A real is $\Pi^0_1$-Martin-Löf random if it does not belong to any $\Pi^0_1$-Martin-Löf test. We have the following result.

Theorem 2.2 (Chong, Nies and Yu [2]). If $\omega_1^* = \omega_1^{CK}$, then $x$ is $\Delta^1_3$-random if and only if $x$ is $\Pi^0_1$-Martin-Löf random.
For an open set $U$, we also identify it as a set of finite strings. For any finite string $\sigma \in 2^{<\omega}$, we use $[\sigma]$ to denote the open set $\{x \mid x \succ \sigma\}$. For any tree $T$, we use $[T]$ to denote the closed set $\{x \mid \forall n (x \in T)\}$.

For more information about randomness and computability theory, see [11] and [3].

3. SOME BASIC FACTS

The following facts are immediate and probably known. Many of them can be found in [5].

**Proposition 3.1.**

1. The collection of Kurtz random reals is $\Pi^0_2$ but not $\Pi^0_3$;
2. The collection of Schnorr random reals is $\Pi^0_4$;
3. The collection of 1-random reals is $\Sigma^0_3$;
4. The collection of weakly 2-random reals is $\Pi^0_3$ but not $\Pi^0_4$;
5. The collection of $\Delta^1_1$-random reals is $\Pi^0_4$.

**Proof.**

1. Obviously the collection of Kurtz random reals $K$ is $\Pi^0_2$. Suppose that $K$ is $\Pi^0_3$. Then there is a recursive set $R \subseteq \omega \times \omega \times 2^{<\omega}$ so that $x \in K$ if and only if $\forall n \exists m R(n, x \upharpoonright m)$. For each $n$, let $K_n = \{x \mid \exists m R(n, x \upharpoonright m)\}$. Then $K_n$ is $\Sigma^0_3$, co-null and $K \subseteq K_n$ for every $n$. Then it would be easy to computably construct a sequence finite strings $\sigma_0 \prec \sigma_1 \ldots$ so that $[\sigma_n] \subseteq K_n$ for every $n$. Then the computable real $x = \bigcup_{n \in \omega} \sigma_n \in \bigcap_{n \in \omega} K_n = K$ would be Kurtz random, a contradiction.

2. Obviously (see [5]).

3. Obviously.

4. Obviously the collection of weakly 2-random reals $W$ is $\Pi^0_3$. Suppose that $W$ is $\Pi^0_4$. Then there is a computable set $R \subseteq \omega \times \omega \times \omega \times 2^{<\omega}$ so that $x \in W$ if and only if $\forall n \exists m \forall j R(n, m, x \upharpoonright j)$. For each $n$, let $W_n = \{x \mid \exists m \forall j R(n, m, x \upharpoonright j)\}$ and $W_{n,m} = \{x \mid \forall j R(n, m, x \upharpoonright j)\}$. Then $K_n$ is $\Sigma^0_3$, co-null and $W \subseteq W_n$ for every $n$. We $\emptyset'$-computably construct a sequence finite strings $\sigma_0 \prec \sigma_1 \ldots$ and $\Pi^0_4$ positive measure sets $T_0 \supseteq T_1 \supseteq T_2 \ldots$ so that $\sigma_n \in T_n$ as follows: $\sigma_0 = \emptyset$ and $W_0 = 2^{\omega}$. Given $\sigma_n$ and $R_n$, Since $W_{n+1}$ is co-null, we may $\emptyset'$-computably find the least $m$ so that $T_n \cap W_{n,m} \cap [\sigma_n] = \{x \succ \sigma_n \mid x \in [T_n] \land \forall j R(n, m, x \upharpoonright j)\}$ has positive measure. Let $T_{n+1} = T_n \cap W_{n,m} \cap [\sigma_n]$ and $\sigma_{n+1}$ be a finite string in $T_{n+1}$ extending $\sigma_n$. Then the $\emptyset'$-computable real $x = \bigcup_{n \in \omega} \sigma_n \in \bigcap_{n \in \omega} W_n = W$ is weakly-2-random, a contradiction to Theorem 2.1.

5. Obviously.

The results above about descriptive complexity of the collections of Kurtz random and 1-random reals are rigid.

**Proposition 3.2.**

1. The collection of Kurtz random reals is not $\Sigma^0_3$;
2. The collection of 1-random reals is not $\Pi^0_2$.

**Proof.**

1. Otherwise, there is a sequence closed sets $\{P_n\}_{n \in \omega}$ such that $\bigcup_n P_n$ contains exactly all the Kurtz random reals. Since all the generic reals are Kurtz random, $\bigcup_n P_n$ is comeager. Then there must be some $n$ so that $P_n$ is not meager. Then $P_n$ must contain an interval and so contain a computable real, a contradiction.

2. Otherwise, there is a sequence open sets $\{U_n\}_{n \in \omega}$ such that $\bigcap_n U_n$ contains exactly all the 1-random reals. Then for every $n$, $\mu(U_n) = 1$. So every $U_n$ is dense. So every sufficient generic real would belong to $\bigcap_n U_n$. But no 1-generic reals can be random, a contradiction to 2.1.

The second result above can be found in [5].
4. Weak 2-randomness

In this section, we prove that the collection of weakly 2-random reals is not $\Sigma^0_2$. We apply a forcing argument.

**Definition 4.1.** Define a forcing notion $\mathbb{P} = (\mathbb{P}, \leq)$ as follows:

1. $P \in \mathbb{P}$ if and only if $P$ is a $\Pi^0_1$-class with positive measure;
2. For $P, Q \in \mathbb{P}$, $P \leq Q$ if and only if $P \subseteq Q$.

Let $\{F_m\}_{m \in \omega}$ be an increasing sequence $\Pi^0_1$ sets so that $\bigcup_{m \in \omega} F_m$ is of measure 1. Set $C = \bigcup_{m \in \omega} F_m$. Let $\mathcal{D}_C = \{P \mid P \in \mathbb{P} \land P \subseteq C\}$.

**Lemma 4.2.** $\mathcal{D}_C$ is dense.

**Proof.** Suppose that $\{F_m\}_{m \in \omega}$ be an increasing sequence $\Pi^0_1$ sets so that $\bigcup_{m \in \omega} F_m$ is of measure 1 and $C = \bigcup_{m \in \omega} F_m$. Let $P \in \mathbb{P}$. Then there is some big enough $m$ so that $\mu(F_m) > 1 - \frac{\mu(P)}{2}$. So $\mu(F_m \cap P) = \mu(F_m) + \mu(P) - \mu(F_m \cup P) > 1 - \frac{\mu(P)}{2} + \mu(P) + 1 = \frac{\mu(P)}{2}$.

Thus $F_m \cap P \in \mathcal{D}_C$. $\square$

The following lemma is a stronger version of Lemma 2.2 in [1].

**Lemma 4.3.** For every computable tree $T$, there is a generalized Martin-Löf test $\{V_n\}_{n \in \omega}$ so that for any $\sigma$, if $[\sigma] \cap [T]$ is not empty, then $[\sigma] \cap [T] \cap \bigcap_n V_n$ is not empty.

**Proof.** The idea is to build a uniformly sequence c.e. open sets $\{V_n\}_{n \in \omega}$ densely meeting $[T]$. The method is just like to build a null comeager set. But we may make some mistakes since there is no effective way to predicate whether $[\sigma] \cap [T]$ is not empty. So, at every step, we need to “correct” the construction of the previous steps. But the measure of mistakes will become very small whenever the step is large enough. This is the reason we can make sure that $\{V_n\}_{n \in \omega}$ is a generalized Martin-Löf test.

Fix a computable tree $T$. So there a computable approximation of computable trees $\{T_s\}_{s \in \omega}$ to $T$ so that

1. $T_0 = T$;
2. $T_{s+1} = \{\sigma \mid \sigma \in T \land \exists \tau \in 2^{s+1} \cap T(\tau \text{ is compatible with } \sigma)\}$;

Then for every $s$, $T_{s+1} \subseteq T_s$.

Fix a computable enumeration $\{\sigma_i\}_{i \in \omega}$ of $2^\omega$ and an enumeration of finite string $\{\sigma_i^{s+1}\}_{i \leq 2^{s+1}}$ of $2^{s+1}$ for each $s$.

We construct $V_0$ for every $n$ step by step.

At step 0, we put $\lambda$ into $V_0$. So the open set $V_0 = 2^\omega$.

At step $s + 1$.

Substep 1: We correct $\{V_k\}_{k \leq s}$ step by step.

Substep 1.0: Check whether there is a $\sigma \in T_{s+1} \cap 2^{s+1}$. If so, then do nothing. Otherwise, stop the construction.

Substep 1.k: Check whether there is some $\tau \in V_k$ so that there is no $\nu \in T_{s+1} \cap 2^{s+1}$ so that $\nu \succ \tau$. If so, check whether there is some $\tau' \succ \tau \upharpoonright k$ in $2^{\tau}$ so that there is a $\nu \in T_{s+1} \cap 2^{s+1}$ so that $\nu \succ \tau'$. If so, then put $\tau'$ into $V_j$ for any $j \leq k$. Otherwise, do nothing.

Substep 2: For every $i$, check whether there is some $\tau \in T_{s+1}$ extending $\sigma_i^{s+1}$. If not, we go to $i + 1$; Otherwise, check whether there is some $\tau \in V_k$ so that $\tau \succ \sigma_i^{s+1}$: if yes, then put $\tau$ into $V_{s+1}$; Otherwise, check whether there is some very long $\tau \succ \sigma_i^{s+1}$ in $T_{s+1}$ so that is longer than any finite strings mentioned before. If yes, pick up such a $\tau$ and put it into $V_{s+1}$. Otherwise, do nothing.
Now for any $k \leq s$, check whether there is some $\tau' \in V_k$ compatible with $\tau$. If yes, do nothing; otherwise, put $\tau$ into $V_s$.

This finishes the construction.

By the construction, for any $n$, $V_{n+1} \subseteq V_n$.

If $\sigma \in T$ and $[\sigma] \cap [T] \neq \emptyset$, then there is some stage $s_0 \geq |\sigma|$ at which we find some $\sigma_0 \succ \sigma$ so that $\sigma_0 \in T$ and $[\sigma_0] \cap [T] \neq \emptyset$. Then there is some large stage $s_1 \geq |\sigma_0|$ at which we find some $\sigma_1 \succ \sigma_0$ so that $\sigma_1 \in T$ and $[\sigma_1] \cap [T] \neq \emptyset$ and put it into $V_{[\sigma_1]}$, etc. Since $\bigcap_{n \in \omega} = \bigcap_{n \in \omega} V_{[\sigma_1]}$, there are reals $x = \bigcup_{n \in \omega} \sigma_i \in (\bigcap_{n \in \omega} V_n) \cap T$. In other words, $[\sigma] \cap [T] \cap \bigcap_{n \in \omega} V_n$ is not empty.

To see that $\{V_n\}_{n \in \omega}$ is a generalized Martin-Löf test, it is sufficient to show $\lim_{n \to \infty} \mu(V_n) = 0$.

For any $i$, there is a big enough $s > i + 1$ so that the open set $E_s = \{\sigma \in 2^s : \sigma \in T_s\}$ has measure less than $\mu([T]) + 2^{-i-1}$. Then from the step $i$ of the construction, except the correction substep, we only put a prefix free set of finite strings into $V_i$. Moreover, except those strings putting at correction substep, for different strings in $V_i$, they have different lengths greater equal to $s$. But at the correction substep, by the assumption of $E_s$, we put at most $2^{-i-1}$ measure of finite strings into $V_i$. So

$$\mu(V_s) \leq \sum_{t \geq s} 2^{-t} + 2^{-i-1} = 2^{-s+1} + 2^{-i-1} \leq 2^{-i-1} + 2^{-i-1} = 2^{-i}.$$ 

Thus $\lim_{n \to \infty} \mu(V_n) = 0$.

For any $\Pi^0_3$ set $G$, let $D_G = \{P \mid P \in P \land P \land \neg G = \emptyset\}$.

Lemma 4.4. If $G$ is a $\Pi^0_3$ only containing weakly-2-random reals, then the set $D_G = \{P \mid P \in P \land P \land \neg G = \emptyset\}$ is dense in $P$.

Proof. Suppose that $G$ is $\Pi^0_3$ only containing weakly-2-random reals. Let $\{U_n\}_{n \in \omega}$ be a sequence of open sets so that $G = \bigcap_{n \in \omega} U_n$. Let $P \in P$. Without loss of generality, we may assume that for any $\sigma$, if $[\sigma] \cap P \neq \emptyset$, then $\mu([\sigma] \cap P) > 0$ (since we may assume that $P$ contains 1-random reals). Then we claim that there is some $\sigma$ so that $P \cap [\sigma] \cap G = \emptyset$ but $P \cap [\sigma] \neq \emptyset$.

Suppose not. By Lemma 4.3, there is a generalized Martin-Löf test $\{V_n\}_{n \in \omega}$ so that for any $\sigma$, if $[\sigma] \cap P \neq \emptyset$, then $\mu([\sigma] \cap P) > 0$. Then we build a sequence strings $\sigma_0 \rightarrow \sigma_1 \rightarrow \sigma_2 \rightarrow \cdots$ as follows.

Let $\sigma_0 = \emptyset$. Now suppose $[\sigma_i] \cap P \neq \emptyset$. Let $\tau \succ \sigma_i$ so that $[\tau] \cap P \neq \emptyset$ and $[\tau] \cap P \subseteq V_i$. By the property of $\{V_n\}_{n \in \omega}$, there exists such a $\tau$. Then by the assumption, let $\sigma_{i+1} \succ \tau$ so that $[\sigma_{i+1}] \cap P \subseteq U_i$.

Let $x = \bigcup_{i \in \omega} \sigma_i$. Then $x \in P \cap (\bigcap_{n \in \omega} U_n) \cap (\bigcap_{n \in \omega} V_n)$. Since $x \in \bigcap_{n \in \omega} V_n$, $x$ is not weakly-2-random, which contradicts to the fact that $G$ only contains weakly-2-random reals.

So there is some $\sigma$ so that $P \cap [\sigma] \cap G = \emptyset$ but $P \cap [\sigma] \neq \emptyset$. Let $Q = P \cap [\sigma]$. Then $Q \in P$ and $Q \subseteq P$.

Theorem 4.5. The collection of weakly 2-random reals is not $\Sigma^0_4$.

Proof. Suppose not. Then there is a countable sequence $\Pi^0_3$ sets $\{G_n\}_{n \in \omega}$ such that the set $\bigcup_n G_n$ contains exactly all the weakly-2-random reals. Then $G_n$ contains weakly 2-random reals for every $n$. Then by Lemma 4.4, for any sufficient generic real $g$ over $\mathbb{P}$, $g \notin G_n$ for any $n$. By Lemma 4.2, for any sufficient generic real $g$ over $\mathbb{P}$, $g$ is weakly-2-random, a contradiction.
5. SCHNORR RANDOMNESS

In this section, we give another proof that the collection of Schnorr random reals is not $\Sigma^0_3$. We use a similar method to the previous section with some modifications.

**Definition 5.1.** Define a forcing notion $Q = (Q, \leq)$ as follows:

1. $Q \in Q$ if and only if $Q$ is a $\Pi^0_1$-class with some computable positive measure;
2. For $P, Q \in Q$, $P \leq Q$ if and only if $P \subseteq Q$.

For any Schnorr test $\{U_n\}_{n \in \omega}$ with $\mu(U_n) = 2^{-n}$ for every $n$, set $U = \bigcap_n U_n$. Let $D_U = \{P | P \in Q \land P \cap U = \emptyset\}$.

**Lemma 5.2.** $D_U$ is dense.

**Proof.** Suppose that $\{U_n\}_{n \in \omega}$ is a Schnorr test with $\mu(U_n) = 2^{-n}$ for every $n$, $U = \bigcap_n U_n$ and $P \in Q$. Then there is some big enough $n$ so that $\mu(U_n) < \frac{\mu(P)}{2}$. Then the complement $P_0 = 2^\omega - U_n$ has measure greater or equal to $1 - \frac{\mu(P)}{2}$. So $P_0 \cap P$ has measure greater or equal to $\frac{\mu(P)}{4}$. We show that $\mu(P_0 \cap P)$ is a computable real. Both $P$ and $P_0$ can be represented by computable trees $T$ and $T^0$ respectively. Since both $P$ and $P_0$ belong to $Q$, for any $i$, we may computably find some big enough $s_i$ such that $\mu((\bigcup_{\sigma \in E_i} [\sigma]) - P) < 2^{-i-1}$ and $\mu((\bigcup_{\sigma \in E_i} [\sigma]) - P_0) < 2^{-i-1}$ where $E_i = \{\sigma \in 2^{n_i} | \sigma \in T\}$ and $E_i^0 = \{\sigma \in 2^{n_i} | \sigma \in T^0\}$. Then

$$\mu((\bigcup_{\sigma \in E_i \cap E_i^0} [\sigma]) - (P \cap P_0)) = \mu((\bigcup_{\sigma \in E_i \cap E_i^0} [\sigma]) - P) \cup ((\bigcup_{\sigma \in E_i \cap E_i^0} [\sigma]) - P_0) \leq 2^{-i-1} + 2^{-i-1} = 2^{-i}.$$ 

So

$$\mu((\bigcup_{\sigma \in E_i \cap E_i^0} [\sigma]) - 2^{-i} \leq \mu(P \cap P_0) \leq \mu((\bigcup_{\sigma \in E_i \cap E_i^0} [\sigma]).$$

Thus $\mu(P \cap P_0)$ is computable. In other words, $P \cap P_0 \in Q$. $\square$

Now we want to mimic the proof of Lemma 4.4. But there is a problem. In the proof of Lemma 4.4, we can make sure that, for any condition $P \in P$, $\mu(\sigma \cap P) > 0$ whenever $\sigma \cap P$ is not empty. The reason is that we can make sure that $P$ only contains 1-random reals. But every condition $Q \in Q$ contains a computable real. So we have to be more careful.

**Lemma 5.3.** For every computable tree $T$ for which $\mu([T]) > 0$ is computable, there is a Schnorr test $\{V_n\}_{n \in \omega}$ so that for any $\sigma$, if $\mu(\sigma \cap [T]) > 0$, then $\mu(\sigma \cap [T \cap V_n]) > 0$ for each $n$.

**Proof.** Suppose that $T$ is a computable tree such that $\mu([T]) > 0$ is computable. Then there is a computable function $f : \omega \rightarrow \omega$ so that for every $s$, $\frac{|E_{f(s)}|}{2^{f(s)}} - \mu(T) < 2^{-s}$ where $E_s = \{\sigma \in 2^{t} | \sigma \in T\}$. Fix a computable enumeration $\{\sigma_i\}_{i \in \omega}$ of $2^{\omega}$ and an enumeration of finite string $\{\sigma_{i+1}^s\}_{i \leq 2^{s+1}}$ of $2^{s+1}$ for each $s$. We define $U_0 = \bigcup_{s} U_0[s]$ as follows:

At step 0, do nothing.
At step $s + 1$. Select the last index $i$ such that

1. There is no $\tau \geq \sigma_i$ belonging to $U_0[s]$;
2. $|\sigma_i \cap E_{f(s)}| > 2^{f(s) - s + 1}.

Then pick up any $2^{f(s) - s + 1}$ many finite strings in $\sigma_i \cap E_{f(s)}$ and put them into $U_0[s + 1]$. Then by the definition of $f$, $U_0[s + 1] \cap [\sigma_i \cap [T] \neq \emptyset$. Obviously at any stage $s + 1$, $\mu(U_0[s + 1] - U_0[s]) < 2^{-s+2}$. So $\mu(U_0)$ is computable. Moreover, for any $\sigma$, if $\mu(\sigma \cap [T]) > 0$, then
µ[σ] ∩ [T] ∩ U_0 > 0. If not, pick up the least index i such that µ([σ_i] ∩ [T]) > 0 but µ([σ] ∩ [T] ∩ U_0) = 0. Then there is a large enough stage s_0 so that for each j < i, if µ([σ_j] ∩ [T]) > 0, then µ([σ_j] ∩ [T] ∩ U_0[s_0]) > 0. Suppose that µ([σ_i] ∩ [T]) > 2^{-k}, then at any stage t > s_0 + k, \|σ_i\| ∩ E_{f(t)} > 2^{f(t) - k} > 2^{f(t) - t + 1}. Then we pick up any 2^{f(t) - t + 1} many finite strings in [σ_i] ∩ E_{f(t)} and put them into U_0[t]. Then µ([σ_i] ∩ [T] ∩ U_0[t]) > 2^{-t}, a contradiction.

Generally, for each n, we define U_n = \bigcup U_n[s] as follows:
At step 0, do nothing.
At step s + 1. Select the lest index i such that
1) There is no τ ≥ σ_i belonging to U_0[s];
2) \|σ_i\| ∩ E_{f(s + n)} > 2^{f(s + n) - s - n + 1}.

Then pick up any 2^{f(s + n) - s - n + 1} many finite strings in [σ_i] ∩ E_{f(s + n)} and put them into U_n[s + 1].

By the same argument above, for every s, µ(U_n[s + 1] - U_n[s]) < 2^{-s - n + 2}. So for any n, µ(U_n) < 2^{-n + 3} is computable. Moreover, for any σ, if µ([σ] ∩ [T]) > 0, then µ([σ] ∩ [T] ∩ U_0) > 0.

Now define V_n = \bigcup_{m ≥ n} U_m. Then µ(V_n) < 2^{-n + 4} for each n. Then by an easy calculation, \{µ(V_n)\}_{n ∈ ω} is uniformly computable. Thus \{V_n\}_{n ∈ ω} is a Schnorr test. By the property of \{U_n\}_{n ∈ ω}, for any σ and n, if µ([σ] ∩ [T] ∩ U_n) > 0, then µ([σ] ∩ [T] ∩ V_n) > 0. □

For any Π^0_1 set G, let D_G = \{P \mid P ∈ Q ∧ P ∩ G = ∅\}.

Lemma 5.4. If G is a Π^0_1 only containing Schnorr random reals, then the set D_G = \{P \mid P ∈ P ∧ P ∩ G = ∅\} is dense in Q.

Proof. Suppose that G is a Π^0_1 only containing Schnorr random reals. Let \{U_n\}_{n ∈ ω} be a sequence open sets so that G = \bigcap U_n. Let P ∈ Q. Then we claim that there is some σ so that P ∩ [σ] ∩ G = ∅ but µ(P ∩ [σ]) > 0.

Suppose not. By Lemma 5.3, there is a Schnorr test \{V_n\}_{n ∈ ω} so that for any σ, if µ([σ] ∩ P) > 0, then µ([σ] ∩ P ∩ V_n) > 0 for each n. Then we build a sequence strings σ_0 < σ_1... as follows.

Let σ_0 = ∅. Now suppose µ([σ_i] ∩ P) > 0. Let τ > σ_i so that µ([τ] ∩ P) > 0 and [τ] ∩ P ⊆ V_i. By the property of \{V_m\}_{m ∈ ω}, there exists such a τ. Then by the assumption, let σ_{i+1} > τ so that [σ_{i+1}] ∩ P ∩ G ≠ ∅. Since G only contains Schnorr random reals, µ([σ_{i+1}] ∩ P ∩ U_i) > 0. Then we may assume that [σ_{i+1}] ∩ P ⊆ U_i and µ([σ_{i+1}] ∩ P) > 0.

Let x = \bigcup_{σ ∈ ω} σ_i. Then x ∈ P ∩ (\bigcap_{n ∈ ω} U_n) ∩ (\bigcap_{n ∈ ω} V_n). Since x ∈ \bigcap_{n ∈ ω} V_n, x is not Schnorr random which contradicts to that G only contains Schnorr random reals.

So there is some σ so that P ∩ [σ] ∩ G = ∅ but µ(P ∩ [σ]) > 0. Let Q = P ∩ [σ]. Then Q ∈ Q and Q ≤ P. □

Theorem 5.5 (Hitchcock, Lutz and Terwijn [5]). The collection of Schnorr random reals is not Σ^0_2.

Proof. Suppose not. Then there is a countable sequence Π^0_1 sets \{G_n\} such that the set \bigcup G_n contains exactly Schnorr random reals. Then by Lemma 5.2 and Lemma 5.4, for any sufficient generic real g over Q, g is Schnorr random but g ∉ G_n for any n, a contradiction. □

We want to point out that the forcing Q does not produce a 1-random real. To see this, fix a universal Martin-Löf test \{U_n\}_{n ∈ ω}. For each n, let D_n = \{P ∈ Q \mid P ⊆ U_n\}.

Corollary 5.6. For each n, D_n is dense.

Proof. Let P ∈ Q and G = 2^ω - U_n. Then G is a Π^0_1 class only containing 1-random reals. Then by Lemma 5.4, there is some Q ≤ P such that Q ∈ D_n.

So if g is sufficient generic over Q, then g is Schnorr random but not 1-random.
6. $\Delta^1_1$-RANDOMNESS

In this section, we prove that the collection of $\Delta^1_1$-random reals is not $\Sigma^0_3$. Some basic facts in higher randomness theory can be found in [13], [6] and [2].

**Definition 6.1.** Define a forcing notion $\mathbb{D} = (D, \leq)$ as follows:

1. $P \in D$ if and only if $P$ is a $\Delta^1_1$, closed set of reals with positive measure;
2. For $P, Q \in D$, $P \leq Q$ if and only if $P \subseteq Q$.

For any $\Delta^1_1$-sequence of $\Delta^1_1$-open sets $\{U_n\}_{n \in \omega}$ with $\lim_{n \to \infty} \mu(U_n) = 0$, set $U = \bigcap_n U_n$. Let $\mathcal{D}_U = \{P \mid P \in D \wedge P \cap U = \emptyset\}$.

**Lemma 6.2.** $\mathcal{D}_U$ is dense.

*Proof.* Suppose that $\{U_n\}_{n \in \omega}$ is a $\Delta^1_1$-sequence of $\Delta^1_1$-open sets with $\lim_{n \to \infty} \mu(U_n) = 0$, $U = \bigcap_n U_n$ and $P \in D$. Then there is some big enough $n$ so that $\mu(U_n) < \frac{\mu(P)}{2}$. Then the complement $P_0 = 2^n - U_n$ has measure greater or equal to $1 - \frac{\mu(P)}{2}$. So $P_0 \cap P$ is a $\Delta^1_1$, closed set and has measure greater or equal to $\frac{\mu(P)}{2}$. Thus $P \cap P_0 \in D$. \hfill $\square$

For any $\Pi^0_1$ set $G$, let $\mathcal{D}_G = \{P \mid P \in D \wedge P \cap G = \emptyset\}$.

**Lemma 6.3.** If $G$ is a $\Pi^0_1$ only containing $\Delta^1_1$-random reals, then the set $\mathcal{D}_G = \{P \mid P \in G \cap \mathcal{D}_G = \emptyset\}$ is dense in $\mathbb{D}$.

*Proof.* Suppose that $G$ is a $\Pi^0_1$ only containing $\Delta^1_1$-random reals. Let $\{U_n\}_{n \in \omega}$ be a sequence open sets so that $G = \bigcap_n U_n$. Let $P \in D$. Then there is a hyperarithmetic real $x$ so that $P$ is $\Pi^0_1(x)$. Without loss of generality, we may assume that for any $\sigma$, if $[\sigma] \cap P \neq \emptyset$, then $\mu([\sigma] \cap P) > 0$ (since we may assume that $P$ only contains $1$-$\sigma$-random reals). Then we claim that there is some $\sigma$ so that $P \cap [\sigma] \cap G = \emptyset$ but $P \cap [\sigma] \neq \emptyset$.

Suppose not. By Lemma 4.3 relativizing to $x$, there is a generalized $x$-Martin-Löf test $\{V_n\}_{n \in \omega}$ so that for any $\sigma$, if $[\sigma] \cap P$ is not empty, then $[\sigma] \cap P \cap (\bigcap_n V_n)$ is not empty. Then we build a sequence strings $\sigma_0 < \sigma_1 \ldots$ as follows.

Let $\sigma_0 = \emptyset$. Now suppose $[\sigma_i] \cap P \neq \emptyset$. Let $\tau \succ \sigma_i$ so that $[\tau] \cap P \neq \emptyset$ and $[\tau] \cap P \subseteq V_i$. By the property of $\{V_n\}_n$, there exists such a $\tau$. Then by the assumption, let $\sigma_{i+1} \succ \tau$ so that $[\sigma_{i+1}] \cap P \subseteq U_i$.

Let $z = \bigcup_{i \in \omega} \sigma_i$. Then $z \in P \cap (\bigcap_n U_n) \cap (\bigcap_n V_n)$. Since $z \in \bigcap_n V_n$, $z$ is not weakly $2$-$x$-random. But $x$ is hyperarithmetic, $z$ is not $\Delta^1_1$-random, which contradicts to that $G$ only contains $\Delta^1_1$-random reals.

So there is some $\sigma$ so that $P \cap [\sigma] \cap G = \emptyset$ but $P \cap [\sigma] \neq \emptyset$. Let $Q = P \cap [\sigma]$. Then $Q \in D$ and $Q \leq P$. \hfill $\square$

So by the same proof as in the previous sections, we have the following result.

**Proposition 6.4.** The collection of $\Delta^1_1$-random reals is not a $\Sigma^0_3$-set.

We give an application Proposition 6.4.

It was very difficult to separate $\Pi^1_1$-Martin-Löf randomness from $\Delta^1_1$-random. The proof in [2] is pretty involved and only contains a sketch. Now we may apply the previous results to give a simpler proof (and even a stronger result).

An immediate conclusion of Proposition 6.4 is:

**Corollary 6.5** (Chong, Nies and Yu [2]). There is a $\Delta^1_1$-random real $z$ which is not $\Pi^1_1$-Martin-Löf random.
For each $x \geq_h \emptyset'$, there is a $\Delta^1_1$-random real $z \equiv_h x$ which is not $\Pi^1_1$-Martin-Löf random.

Proof. The collection of $\Pi^1_1$-Martin-Löf random is a $\Sigma^0_9(\emptyset)$-set. Moreover, there is a $\emptyset'$-computably enumerable enumeration of the conditions in $D$ (see Sacks [13]). Then hyperarithmetically in $\emptyset'$, by a finite extension argument, it is not difficult to construct a $\Delta^1_1(\emptyset')$-perfect tree $T$ so that every infinite path in $T$ is a $\Delta^1_1$-random but not $\Pi^1_1$-Martin-Löf random. By Theorem 2.2, every real $x \in [T]$ is hyperarithmetically above $\emptyset$. So for each $x \geq_h \emptyset'$, there is a $\Delta^1_1$-random real $z \equiv_h x$ which is not $\Pi^1_1$-Martin-Löf random.

We want to point out an observation there. In [13], Sacks does not use a forcing argument to study measure theoretic uniformity. In stead of that, he uses a model $\mathcal{M}(\omega^1_{CK}, x)$. The advantage of his method is to show that $\mathcal{M}(\omega^1_{CK}, x)$ satisfies $\Delta^1_1 - CA$ (and so $\omega^1_{CK} = \omega^1_{CK}$) for almost all reals $x$. Now the reason that a forcing argument is avoided seems clear since the forcing notion with $\Delta^1_1$-sets with positive measures does not produce a generic real $x$ with $\omega^1_{CK} = \omega^1_{CK}$.

7. Some remarks

We don’t know what’s the exact complexity of the collection of $\Pi^1_1$-random reals. We conjecture that it cannot be a $\Sigma^0_{\omega^1_{CK}} = \bigcup_{\alpha < \omega^1_{CK}} \Sigma^0_{\alpha}$.

For any cardinal $\kappa$ and number $n$, we use $\kappa - \Sigma^0_{n+1}$ to denote the class of the sets which can be a union of less than $\kappa$-many $\Pi^0_n$-sets. For example, $\aleph_1 - \Pi^0_3$-class is exactly same as $\Sigma^0_{\aleph_1}$-class. We also can define $\kappa - \Pi^0_{\aleph_1}$-class in the similar way. Then the following is true.

Theorem 7.1. Assuming ZFC + Martin’s axiom, then

1. The collection of Kurtz random reals is not $2^{\aleph_0} - \Sigma^0_3$;
2. The collection of Schnorr random reals is not $2^{\aleph_0} - \Sigma^0_3$;
3. The collection of 1-random reals is not $2^{\aleph_0} - \Pi^0_3$;
4. The collection of weakly 2-random reals is not $2^{\aleph_0} - \Sigma^0_3$;
5. The collection of $\Delta^1_1$-random reals is not $2^{\aleph_0} - \Sigma^0_3$.

Proof. All the negative results in the previous sections were proved by c.c.c. forcings except (1) and (3). But it is a theorem under ZFC + Martin’s axiom that any set which is a union of less than $2^{\aleph_0}$ many meager sets is meager (see [7]). So under ZFC + Martin’s axiom, (1)-(5) all are true.

We don’t know whether the conclusions of Theorem 7.1 can be proved under ZFC. We don’t either know whether the following question is known.

Question 7.2. Is it consistent with ZFC + ¬CH that every $\Pi^1_1$-set is a union of $\aleph_1$-many closed sets?
